

ABSTRACT OF THE DISCLOSURE

A print control device including an acquisition unit for acquiring print conditions in response to a print request, a fixing unit for fixing a frequency of determining a print cancel based on the print conditions acquired by the acquisition unit, and a determining unit for determining whether a print cancel command is issued as the data processing unit generates and/or transfers print data at the frequency fixed by the fixing unit. The print control device thus determines the presence or absence of a print cancel command at an appropriate frequency under an environment that permits no multitasking. A response process from the reception of the print cancel command to the execution of a cancel operation becomes uniform, resulting in unnecessary waiting time and useless printing actions.
